Abstract:	Effective regulation of emotion is one of the most important skills that develops in childhood. Research interest in this area is expanding, but empirical work has been limited by predominantly correlational investigations of children's skills. Relatedly, a key conceptual challenge for emotion scientists is to distinguish between emotion responding and emotion regulatory processes. This paper presents a novel method to address these conceptual and methodological issues in child samples. An experimental paradigm that assesses the effectiveness with which children regulate emotion is described. Children are randomly assigned to use specific emotion regulation strategies, negative emotions are elicited with film clips, and changes in subsequent psychophysiology index the extent to which emotion regulation is effective. Children are instructed to simply watch the emotion-eliciting film (control), distract themselves from negative emotions (cognitive distraction), or reframe the situation in a way that downplays the importance of the emotional event (cognitive reappraisal). Cardiac physiology, continuously acquired before and during the emotional task, serves as an objective measure of children's unfolding emotional responding while viewing evocative films. Key comparisons in patterns of obtained physiological reactivity are between the control and emotion regulation strategy conditions. Representative results from this approach are described, and discussion focuses on the contribution of this methodological approach to developmental science.

July 4, 2016

Dear Dr. Myers,

Thank you for the invitation to submit our paper, "*Psychophysiological Assessment of the Effectiveness of Emotion Regulation Strategies in Childhood*," to the *Journal of Visualized Experiments*. The authors of this manuscript, in order, are myself (Dr. Elizabeth L. Davis), Ms. Parisa Parsafar, Ms. Laura E. Quiñones-Camacho, and Ms. Emily Shih. I will serve as corresponding author for this submission. All authors are in agreement on the format and content of this submission, and this manuscript is not under review elsewhere. All research techniques described in the protocol were approved by the appropriate Institutional Review Boards.

- Our manuscript describes a novel experimental paradigm for studying the effectiveness of emotion regulation in childhood. The procedure involves instructing children to use specific techniques for managing negative emotions (or reacting normally in a Control condition) and assessing cardiac physiological functioning before and during a negative emotion elicitation and online implementation of emotion regulation strategies. The method is not complicated, but is extremely well suited to publication in a multimedia venue given the procedures (e.g., establishing rapport with participants, ensuring child comprehension of the experimental instructions, application of the EKG electrodes to children's torsos), which are much more clearly communicated through visual than text-based channels.
- Each of the four authors contributed substantively to the procedures described in this manuscript, including via data collection, coding, and analysis with this protocol in our laboratory. In addition, each author was involved in drafting and revising the text-based manuscript describing the protocol. If selected for publication, all authors are willing to be video recorded to demonstrate the key steps of the protocol.
- We were invited to submit this paper by Dr. Ronald Myers, and he assisted us in preparing the manuscript.
- We suggest the following individuals as possible reviewers for this submission:
 - Dr. Abbey Alkon, University of California, San Francisco, abbey.alkon@ucsf.edu
 - Dr. Tracy Dennis, Hunter College, City University of New York, tracy.dennis@hunter.cuny.edu
 - Dr. Paulo Graziano, Florida International University, pgrazian@fiu.edu
 - Dr. Paul Hastings, University of California, Davis, pdhastings@ucdavis.edu
 - Dr. Ethan Kross, University of Michigan, ekross@umich.edu
 - Dr. Diane Lickenbrock, Western Kentucky University, diane.lickenbrock@wku.edu

Please do not hesitate to let me know if any additional information is needed. We look forward to hearing from you about this manuscript.

Sincerely,

A handwritten signature in cursive script, appearing to read "E. L. Davis".

Development, childhood, emotion, emotion regulation, respiratory sinus arrhythmia, psychophysiology, experimental design

SHORT ABSTRACT:

A detailed protocol for an experimental paradigm to assess the effectiveness with which children regulate emotion is described. Children are randomly assigned to use specific emotion regulation strategies, negative emotions are elicited with film clips, and changes in subsequent psychophysiology index the extent to which emotion regulation is effective.

LONG ABSTRACT:

Effective regulation of emotion is one of the most important skills that develops in childhood. Research interest in this area is expanding, but empirical work has been

limited by predominantly correlational investigations of children's skills. Relatedly, a key conceptual challenge for emotion scientists is to distinguish between emotion responding and emotion regulatory processes. This paper presents a novel method to address these conceptual and methodological issues in child samples. An experimental paradigm that assesses the effectiveness with which children regulate emotion is described. Children are randomly assigned to use specific emotion regulation strategies, negative emotions are elicited with film clips, and changes in subsequent psychophysiology index the extent to which emotion regulation is effective. Children are instructed to simply watch the emotion-eliciting film (control), distract themselves from negative emotions (cognitive distraction), or reframe the situation in a way that downplays the importance of the emotional event (cognitive reappraisal). Cardiac physiology, continuously acquired before and during the emotional task, serves as an objective measure of children's unfolding emotional responding while viewing evocative films. Key comparisons in patterns of obtained physiological reactivity are between the control and emotion regulation strategy conditions. Representative results from this approach are described, and discussion focuses on the contribution of this methodological approach to developmental science.

INTRODUCTION:

Children experience negative emotions like sadness and fear every day. As they develop and mature, children learn regulatory strategies that allow them to manage a broad range of stressors and challenges to adapt to the world. Their emotion regulation repertoire expands, and shifts in composition from primarily behavioral strategies to include more cognitive strategies¹. By the end of middle childhood, children regulate their emotions using both cognitive and behavioral strategies². Understanding the effective regulation or management of unwanted negative feelings has become increasingly interesting to developmental scientists in recent years. This interest is driven, in part, by research linking emotion regulation processes to a host of social, emotional, and cognitive outcomes with substantial consequences for children's daily lives (e.g., academic achievement³, friendships⁴, and psychopathology⁵).

The method described here focuses on two cognitive emotion regulation strategies that have received the lion's share of empirical attention to date: reappraisal and distraction. Studies done with adults have shown that reappraisal and distraction are effective methods for alleviating emotion⁶⁻¹¹. Reappraisal, which involves changing or reframing *how* one interprets an emotion or problem, has been shown to be effective in reducing the intensity of negative emotions in school-aged children^{12,13}. Distraction, in contrast, involves changing *what* one is thinking about, such as when a child about to receive a vaccine thinks instead of the ice cream they will enjoy with their parent afterwards. Children can also begin to use these cognitive strategies to regulate negative emotions effectively, from as young as 5-6 years of age¹⁴.

The Theoretical and Practical Challenges of Studying Emotion Regulation

Emotional reactivity and regulatory processes are intertwined, bidirectional, and iterative^{15,16}. Thus, a key conceptual challenge for developmental scientists is to identify and employ methods that meaningfully distinguish between emotion responding and

regulatory processes. The approach described here takes the view of emotions as *regulated* (in contrast to emotions as *regulating*)¹⁵. Emotion regulation is defined as the process of changing an experienced emotion¹⁷ in ways that alter the intensity, duration, and/or valence of the emotion¹⁸.

Despite promising behavioral evidence that cognitive emotion regulation strategies like distraction and reappraisal reduce negative emotions¹⁴, there are many limitations to the predominant self-report or observational methodologies that constrain the conclusions that can be drawn from existing empirical studies, especially with young children. For example, self-report of emotional experience is subject to inaccuracies and demand characteristics. Although behavioral observation (e.g., of facial expressions) to index emotional responding is ostensibly more objective than self-report, observation is still subject to automatic and explicit regulatory processes that mask or hide the true experience of distress or negative emotion. To address these conceptual and methodological issues, this paper describes a method of examining the effects of emotion regulation strategies on children's subsequent psychophysiology that allows researchers to more clearly distinguish between *reactivity* to and active *regulation* of negative emotions. This experimental paradigm for eliciting negative emotions and assessing the consequences of different instructed emotion regulation strategies provides an approach that can be used with children of a wide range of ages, adolescents, or adults.

Psychophysiology Is a Non-Invasive Index of Emotion Regulation

Respiratory sinus arrhythmia (RSA) is a commonly used index of parasympathetic cardiac psychophysiology, and has emerged as a key correlate of children's emotion regulatory ability^{19,20}. RSA is derived from the measurement of heart rate variation (controlled by efferent fibers of the vagus nerve) within the respiratory cycle^{21,22}. High baseline RSA indicates better emotional regulation and socio-emotional competencies²¹, whereas lower baseline RSA is linked to negative socio-emotional outcomes²³. Baseline RSA reflects the system's regulatory capacity to respond to stress, whereas changes in RSA from baseline levels under conditions of challenge (RSA reactivity) enable greater sympathetic influence and resource mobilization. This process reflects a shift away from homeostatic demands to the facilitation of sustained attention, behavioral self-regulation, and the generation of coping strategies to control affective or behavioral arousal^{20,26}. RSA reactivity to challenging lab tasks is associated with better emotion regulatory abilities and general adaptive functioning, including less negative emotionality and risk for behavior problems and better sustained attention^{21, 23-27}. RSA reactivity to challenge can be described as increasing (RSA augmentation) or decreasing (RSA suppression) parasympathetic influence. The flexibility with which parasympathetic influence over the heart is regulated across contexts is thought to underlie adaptive emotion regulation.

Indeed, changes in children's RSA amplitudes during a series of challenging tasks predict their emotional regulatory skill²⁸. RSA is responsive in emotionally challenging contexts as well. For example, RSA suppression (a decrease from baseline level to task level) is linked to experiencing fear and sadness, but augmentation (increase from

baseline to task) is linked to effective regulation of emotion when sadness and fear are evoked via film clips^{29,30}. Previous work that has capitalized on the utility of this non-invasive method for assessing *in vivo* emotion regulation processes has demonstrated how children's use of specific cognitive emotion regulation strategies predicted RSA reactivity while they were watching emotion-eliciting videos³¹. This paper describes a novel experimental paradigm developed to use the physiological patterns associated with active emotion regulation to index regulatory ability, providing an innovative method to parse the experience and regulation of negative emotions.

PROTOCOL:

Note: The university's institutional review board approved all procedures before recruitment or data collection with human subjects began. Parents provide informed consent for children's participation, and children provide verbal (or, verbal and written if older than 7 years) assent to participate in these activities.

1. Randomly Assign Participants to Experimental Conditions

1.1) Test the effects of two different emotions and two different emotion regulation strategy instructions against a control group that receives no emotion regulation instructions, using a 2 (discrete emotion condition: sad or scary) x 3 (emotion regulation condition: control, distraction, or reappraisal) between-subjects experimental design.

NOTE: Other experimental designs may also be used, as long as a suitable control group is included against which the effects of interest may be compared. For example, a neutral film condition, in which no emotion is evoked, could be included, or a within-subjects design could be used. Regardless, an approximately equal number of children should be assigned to each experimental condition.

1.2) Randomly assign children to one of the six conditions before they arrive at the laboratory (with the constraint that an approximately equal number of boys and girls are assigned to each condition).

2. Establish Rapport with Child Participants

2.1) The following are procedures for the lead experimenter, E1 to follow. At the beginning of the visit, establish rapport with the child to ensure their compliance with study procedures.

2.2) Sit at a small table with the child, and introduce art supplies the child can use if desired (e.g., crayons, paper). Ask 2-3 questions about the child's hobbies and interests to engage the child in friendly conversation.

2.3) Once the child appears to have acclimated to the laboratory context and is relaxed in his or her interaction (usually about 5-10 minutes), begin other procedures.

3. Train Children to Self-Report Their Emotions

3.1) Train children to self-report the intensity of their emotional reactions (sadness, fear,

happiness) using simple, four-point cartoon face scales to rate each discrete emotion separately (see Figure 1). Each scale depicts a neutral face (“not at all Sad/Scared/Happy”) followed by three faces depicting increasingly exaggerated (*A Little, Pretty Much, Very*) target facial expressions for each emotion.

3.2) Present one scale to the child, and read the scale anchors aloud while pointing to each corresponding face.

Note: Say, “Today we are going to play a lot of different games, and sometimes we will ask you to tell us what you are thinking and feeling. This scale shows some sad faces. You can use this to tell us how sad you are feeling at different times today.”

3.3) Demonstrate use of the scale.

Note: Say: “So, this face is where you would point if you feel ‘Not at All’ sad [*points to first face*]; This one is where you would point if you feel ‘A Little’ sad [*points to second face*]; This one is where you would point if you feel ‘Pretty Much’ sad [*points to third face*]; And this one is where you point if you feel ‘Very’ sad [*points to fourth face*].”

3.4) Repeat this training process for each emotion of interest (e.g., sadness, fear, anger, happiness).

3.5) For each emotion scale, give the child two practice questions to ensure comprehension. If children point to an incorrect face, or express confusion about what to do, repeat the instructions (and practice trials) until children answer two practice items correctly.

Note: Say “(e.g., “Which face would you point to if you felt *very* sad?” and, “Where would you point if you felt *not at all* sad?”).

3.6) After the training trials, explain to the child that they will be asked to report feelings using the same scales a few more times during the study.

[Place Figure 1 Here]

4. Acquire a Baseline Report of Children’s Emotions

4.1) Ask children to self-report how they are “really feeling, *right now*,” using the same 4-point emotion face scales before children receive emotion regulation instructions or view any film clips.

4.2) This self-report constitutes the baseline emotion assessment that is necessary to ensure that children do not feel pre-existing negative emotion that would influence their reaction to the experimental manipulation. Children additionally report their sad, scared, and happy feelings again using this same format after viewing the sad or scary film clip.

5. Acquire Cardiac Psychophysiology Data

5.1) Have the second adult experimenter (E2) enter to assist with electrode placement.

Note: E2 explains that children wear sticky sensors on their torsos so that the experimenters can monitor their hearts during the study.

5.2) Frame electrode placement as a game to improve children's compliance with the procedure. As part of the "sticker game," the child chooses multiple stickers from a sheet and can keep them, place them on the experimenters, place them on their parent, or wear them on their own body.

5.3) Secure stickers (selected by the child) to three disposable, pre-gelled electrodes and place these over the child's distal right collarbone, lower left rib, and lower right rib to acquire the ECG signal.

5.3.1) Ask parents if they are comfortable with E2 placing the electrodes on their children. If not, ask parents to help place the electrodes on their children's torsos, with guidance from E2.

5.4) After attaching the electrodes, give the children 5 minutes to acclimate to wearing the sensors, then acquire a resting parasympathetic baseline. Record baseline electrocardiograph (ECG) for five minutes. During this baseline phase, children sit quietly at a table with E1, coloring or reading a book.

5.5) Continue the ambulatory, wireless ECG recording for the rest of the visit with the ambulatory monitor secured in a child-sized backpack hung on the back of a chair to minimize movement artifacts. ECG signal for ambulatory acquisition is typically sampled at a rate of 500 ms and bandpass filtered at 40 and 250 Hz.

5.6) At the end of the study, gently remove and discard the electrodes NOTE: This is analogous to removing an adhesive bandage in terms of potential discomfort to the participant.

6. Provide Children with Emotion Regulation Instructions

6.1) Based on experimental condition assignment, provide each child with specific, scripted emotion regulation instructions before showing them a film clip designed to evoke negative emotion.

6.1.1) For children assigned to the Control condition

6.1.1.1) Show a short movie to the children and instruct them pay attention to all the things that happen in the movie. Ask questions to the children at the end of the movie.

NOTE: Instructor says: "I'm going to show you a short movie now. Pay close attention to the movie because we will ask you some questions about it later. While you watch this movie, I want you to just try to pay attention to all the things that happen in the movie, ok? Can you try to do that? Ok, so what are you going to try to do while you watch the

movie?”

6.1.2) For children assigned to the Distraction condition

6.1.2.1) Show a short movie to the children and instruct them pay attention to the movie. Instruct the children if they feel bad or upset, then to think about something happy instead. Ask questions to the children at the end of the movie.

NOTE: Instructor says: “I’m going to show you a short movie now. Pay close attention to the movie because we will ask you some questions about it later. While you watch this movie, if you start to feel bad or upset, I want you to think about something happy instead. You could think about a time you had fun playing, or eating ice cream, or think about a TV show you like to watch. Anything that you can think of that is happy is ok to think about instead, ok? Can you try to do that? Ok, so what are you going to try to do while you watch the movie?”

6.1.3) For children assigned to the Reappraisal condition

6.1.3.1) Show a short movie to the children and instruct them pay attention to the movie. Instruct the children if they feel bad or upset, then to think that it’s not really happening. Ask questions to the children at the end of the movie.

NOTE: Instructor says: “I’m going to show you a short movie now. Pay close attention to the movie because we will ask you some questions about it later. While you watch this movie, if you start to feel bad or upset, I want you to think about how everything that is happening in the movie is not really happening, so it’s not a big deal. Think about how it’s just a movie, and isn’t real, ok? Can you try to do that? Ok, so what are you going to try to do while you watch the movie?”

6.2) Provide follow-up questions at the end of the specific instructions to ensure that children understand what they should do. Repeat instructions for any child who expresses confusion about what to do.

NOTE: Follow up question such as, “what are you going to try to do?”

7. Elicit Negative Emotion

7.1) Show children standardized film clips to elicit negative emotions (e.g., sadness or fear). Though a variety of film clips can be chosen, clips should be brief (about 3-5 minutes long), age-appropriate, and acceptable to parents (e.g., films with a G or PG rating should be chosen).

NOTE: Before running the experiment, pilot test the film clips with the target age range to ensure that the expected discrete emotion or negative affective state is evoked with sufficient intensity and specificity. Though sadness and fear are examined in this protocol, other negative and positive emotions can be evoked as desired using other film clips.

7.1.1) Elicit sadness by showing children a brief (~5-minute) scene from *The Land Before Time*³².

NOTE: In the clip, a young dinosaur searches for his mother during a storm. She has been injured and shortly after he finds her and they have a conversation, she dies. The little dinosaur is left alone and lost and cries while he tries to find his way back to the main herd.

7.1.2) Elicit fear by showing children a brief (~5-minute) scene from *The Secret of NIMH*³³.

NOTE: In the clip, a mouse navigates her way through a dark and eerie cave (an owl's lair) to seek help for her son, who is ill. Inside the cave, she trips over piles of bones, and is almost eaten by a giant spider before coming face-to-face with the owner of the cave, a giant scary owl who devours a moth in front of her, and crushes the spider. She has a brief conversation with the owl in which she asks for advice about how to help her son.

7.2) After watching the emotion-eliciting film, ask children to self-report their feelings again using the face scales. Later, compare this second self-report to the baseline emotion rating to ensure the emotion manipulation was effective.

8. Alleviate Intense or Lingering Negative Emotions

8.1) After completion of the task and removal of the electrodes, provide a positive affect emotion induction to ensure children do not leave the laboratory feeling upset.

NOTE: As with the previous film clips, choose a film that is brief (about 3-5 minutes long), age-appropriate, and acceptable to parents (e.g., with a G or PG rating).

8.2) Elicit positive emotion in children by showing a short film (~4-minutes) called *For the Birds*³⁴.

NOTE: In the clip, a bird lands on a telephone wire, is joined by several other birds, and then by a big, awkward looking bird. A series of amusing interactions takes place, and the clip ends with all the birds laughing together.

NOTE: If a child becomes unduly upset at any point during the study, follow ethical guidelines for working with children. If a child seems overly distressed by any aspect of the protocol (e.g., watching the sad or scary film), take a short break. After allowing the child to calm down for ~30 seconds, check to see if the child is ready to continue or if they need a longer break.

NOTE: If a child continues to be excessively distressed, call the parent in to the room to help comfort their child. If the distress persists for longer than a couple of minutes, the child cannot calm down, or the participants wish to discontinue participation (in the task

or study altogether) the protocol should be stopped immediately, and the positive affect induction begun to conclude the visit.

9. Process and Code Physiology Data

9.1) Continuously record electrocardiogram (ECG) throughout the laboratory tasks and process these data offline (as described in 9.2-9.6).

NOTE: Respiratory sinus arrhythmia (RSA), the measure of parasympathetic physiology of interest to index children's online emotion regulation, is derived from the ECG signal using a software program (e.g., Mindware Heart Rate Variability). The Mindware software program allows for behavioral or procedural event markers to be inserted into the physiological data stream on- or off-line.

9.2) Use the heart-rate editing software's validated algorithm³⁵ to detect interbeat intervals (IBIs) and intervals that are physiologically improbable based on the overall distributions of collected data.

9.2.1) After opening the software, select the correct participant file on the data file path. In the events and modes tab enter the correct start and end time of the episode and enter 30s as the segment time.

9.3) In the calibration settings tab, select the high frequency range for the age of children in the study. For children between 3 and 12 years of age, respiratory sinus arrhythmia (RSA) is defined as the natural log integral of the .15 to .8 Hz power band³⁶⁻³⁷

9.3.1) Then, click on the Analyze (ENTER) button on the lower right. Observe a segment of the data appear on the screen with the question "Is the EKG inverted?". Visually inspect the data and respond no if it looks normal or yes if it looks inverted.

9.4) Visually inspect data for artifacts and make corrections as needed. Blue dots indicate that there is no need to edit the data, yellow dots indicate that the data should be carefully inspected and edited.

9.4.1) Click the green "Edit Rs" button at the top to inspect and edit a segment of data. Check the RSA value for each segment on the RSA section on the lower right of the screen. Values should be between 0-10.

9.5) Write the clean and edited data to an spread sheet file using the white "Write" button on the top of the page. When done writing out segments, click the red "Done" button at the top of the screen.

9.5.1) Using the spread sheet file, calculate interrater reliability on ~25% of cases. To constitute a reliable match, final RSA values for any 30s epoch from two scorers should fall within 0.1 of one another^{31,38-39}. Raters should agree on at least 85% of the epochs.

9.6) In the spread sheet file, click on the “HRV stats” tab to retrieve RSA values for each coded segment. Calculate RSA scores for an episode by averaging all segments within the episode.

10. Calculate RSA Reactivity Scores

10.1) Calculate RSA reactivity using one of the methods described below.

10.1.1) First, calculate RSA reactivity as the simple difference between the baseline (sitting quietly) and challenge (watching an emotion-eliciting film) tasks. Subtract the baseline value from the average task value for each participant (e.g., RSA during sad movie = 7.20; RSA during baseline = 7.00; task minus baseline: $7.20 - 7.00 = .20$).

NOTE: In this approach, positive reactivity values indicate that RSA has increased (RSA augmentation) relative to baseline. Include baseline RSA values as a covariate in other analyses to account for individual variation in initial level when characterizing the pattern of change within the experimental context.

10.2) Calculate RSA reactivity as a residualized change score by predicting task RSA from baseline RSA in a linear regression. Save the standardized residuals from this analysis as a new variable. In this approach, positive reactivity values indicate that RSA increased more than sample average.

11. Data Analysis

11.1) Conduct a manipulation check using children’s self-reported emotions.

NOTE: Preliminary analyses (e.g., one-way ANOVA) should compare children’s ratings of each emotion at baseline to ensure that there are no differences in emotion ratings by experimental condition before viewing the films.

11.1.1) Determine whether the emotional films elicited the intended negative emotion by comparing children’s baseline self-report ratings (before film) to ratings provided immediately after the film using paired samples t-tests or ANOVA.

NOTE: Significant increases in target emotion suggest that the films evoked the target emotion. If multiple negative emotions are assessed via self-reports (e.g., sadness and fear), an alternate way to ensure the effectiveness of the emotion elicitation is to compare the intensity of different emotion ratings provided immediately after the film. The target negative emotion (e.g. sadness) should be evoked significantly more strongly than other negative emotions (e.g., anger, fear).

11.2) Examine the effect of emotion regulation instructions on children’s physiological reactivity. Use ANOVA to compare children’s baseline RSA levels across the different emotion regulation instruction conditions and ensure there were no differences in RSA before viewing the film (again serving as a check of the assumptions of random assignment).

NOTE: RSA reactivity (change from baseline to task) that represents an increase from baseline levels (augmentation) is typical when emotions are evoked using film clips²⁹⁻³¹. Examination of average baseline RSA and average task (film viewing) RSA should

show a significant increase in RSA for all participants, regardless of experimental condition.

11.2.1) Examine differences in RSA reactivity patterns among experimental conditions using ANOVA, with covariates included as needed.

NOTE: RSA reactivity is the dependent variable of interest here, but similar procedures can be used to examine other indices of emotional processes (continuous coding of facial expressions, for example).

11.3) To probe ANOVA results, conduct pairwise comparisons to identify the significant differences in RSA reactivity scores between different experimental conditions.

NOTE: Recall that Control group participants are not instructed to use a specific emotion regulation strategy to manage sadness or fear. Thus, key contrasts in RSA reactivity are between the two experimental strategy conditions (Distraction and Reappraisal) and the Control condition.

REPRESENTATIVE RESULTS:

As shown in Figures 2 and 3, a typical result is that instructing children to use cognitive emotion regulation strategies leads to a different pattern of RSA reactivity than simply viewing the emotional film (Control). This supports the idea that instructions to regulate negative emotion using distraction or reappraisal enhance children's parasympathetic calming response during an emotionally challenging task, given the difference in responding among children in the Control condition and the strategy conditions.

Different methods for quantifying RSA reactivity have distinct implications for the interpretation of the results. Figure 2 presents RSA reactivity, computed as a difference score, as the dependent variable. This calculation provides information about the direction (i.e., a positive or negative change in RSA from baseline levels) and magnitude of the change. Positive difference scores indicate RSA augmentation and enhanced parasympathetic influence, in line with the view that emotion regulation strategies promoted calming. In contrast, Figure 3 depicts results of the same analysis with a different computation of RSA reactivity (standardized residuals) used as the dependent variable. These residualized change scores account for the initial level (baseline) of each participant, and quantify the extent to which RSA reactivity is greater than (positive change scores) or less than (negative change scores) the average change for the entire sample. Because reactivity with this second computation is relative to the sample average, interpretation must avoid describing reactivity in absolute terms. Instead, Figure 3 suggests that children in the *Reappraisal* condition showed RSA reactivity comparable to the sample average ($M = 0$), children in the *Distraction* condition showed relatively less RSA augmentation than average, and the reactivity of children in the *Control* condition was greater than average for the sad film, but average for the scary film. Thus, researchers should select the desired statistical approach to quantifying RSA reactivity data that allows for a generalizable (Figure 2) or sample-specific (Figure 3) interpretation.

FIGURE LEGENDS:

Figure 1. Emotion Rating Scale. This scale displays the picture scales that the researcher shows the children throughout the experiment to collect in-the-moment ratings of how sad- scared- and happy they are.

Figure 2. RSA reactivity to the sad and scary films (calculated as a difference score) by emotion regulation condition. This bar graph displays children's RSA reactivity to the sad and scary films in each of the three between-subject instruction conditions (Control, Distraction, Reappraisal). Error bars represent standard error.

Figure 3. RSA reactivity to the sad and scary films (calculated as residualized change scores) by emotion regulation condition. This bar graph displays children's RSA reactivity to the sad and scary films in each of the three between-subject instruction conditions (Control, Distraction, Reappraisal) using the same dataset as Figure 3. Error bars represent standard error.

DISCUSSION:

Critical steps within the protocol

Effectively eliciting negative emotion and instructing children to use specific emotion regulation strategies are the critical steps within the protocol.

Modifications and troubleshooting

Film clips must be selected (and pilot tested) to be age-appropriate given the age range in question to ensure they evoke the target emotions of interest for the specified age ranges. Researchers should also take care to make sure that children understand the emotion regulation instructions. After providing regulatory instructions, researchers should ask children what they will do if they start to feel the target negative emotion (e.g., sad, scared) and ensure that children can repeat the instructions before the film task begins.

Limitations of the technique

Limitations to this technique include the generalizability of physiological regulation from a brief lab-based evocation to real world contexts. For example, film clips are brief in duration and the negative emotions they evoke are often short-lived. People's emotional engagement during a brief clip may be very different from their engagement in real world events, and as such, individual motivation to engage in regulatory strategies and their subsequent performance on lab-based versus real-world emotional challenges may vary widely as well. To the extent that the cognitive emotion regulation strategies examined here impose cognitive load, they could influence RSA differently than other emotion regulation strategies. In addition, alternative baseline tasks and conditions (e.g., watching a neutral film) should be considered in conjunction with the goals of the researcher. Future work should combine physiological assessments of emotion regulation with experiential and behavioral assessments to gain a more comprehensive picture of effective regulation.

Significance of the technique with respect to existing/alternative methods

Given the difficulty in separating the experience of emotion from active regulatory attempts, this approach answers the call for techniques that parse reactive and regulatory processes to provide conceptual and methodological clarity¹⁵. The experimental paradigm demonstrates that engagement in purposeful, active emotion regulation can be quantified by examination of RSA reactivity, and separated from the experience of negative emotions. Findings from this paradigm represent a first step towards understanding how emotion regulation strategies relate to changes in children's emotional responding. This is noteworthy because this work focuses on strategies that are cognitive (such as distraction and reappraisal), making them harder to assess through traditional approaches to examining children's emotional responding in the laboratory (e.g., observations, self-report, parent report). The advantage of this approach is particularly evident early in development when children are less able to articulate or explain their regulatory choices. This psychophysiological method of assessing emotion regulation in children gives the opportunity to acquire information about children's active regulatory processes as they unfold that cannot be acquired through observations and self-reports.

Future applications or directions after mastering this technique

The use of film clips to elicit negative emotions has multiple benefits. Not only does this approach allow for greater levels of experimental control and minimize movement artifacts by having children sit during the tasks, but may also minimize measurement invariance issues, given that films have successfully been used to evoke discrete emotions in child participants across a wide range of ages^{12,31}. Future research can take advantage of this type of paradigm to examine how individual differences (e.g., pre-existing emotional regulatory skill, cognitive functioning, exposure to trauma, personality) can influence people's physiological reactivity in emotional contexts. Such an approach would shed light on the important psychological questions of *which individuals*, or *under which conditions* an individual may benefit more or less from specific emotion regulation strategies.

In sum, this novel lab-based paradigm advances understanding of the interrelation of emotional reactivity and regulation, by providing a controlled technique for eliciting negative emotions and measuring subsequent physiological responding that corresponds to the use of different emotion regulation strategies.

ACKNOWLEDGMENTS:

We thank the children and families who have participated in our studies and the research assistants of the Emotion Regulation Lab for their assistance with data collection and coding.

DISCLOSURES:

The authors have nothing to disclose.

ARTICLE AND VIDEO LICENSE AGREEMENT

Title of Article: Psychophysiological Assessment of the Effectiveness of Emotion Regulation Strategies in Childhood
Author(s): Elizabeth L. Davis, Parisa Parsafor, Laura E. Quiñones-Camacho, & Emily W. Shih

Item 1 (check one box): The Author elects to have the Materials be made available (as described at <http://www.jove.com/publish>) via: ☒ Standard Access ☐ Open Access

Item 2 (check one box):

- ☒ The Author is NOT a United States government employee.
☐ The Author is a United States government employee and the Materials were prepared in the course of his or her duties as a United States government employee.
☐ The Author is a United States government employee but the Materials were NOT prepared in the course of his or her duties as a United States government employee.

ARTICLE AND VIDEO LICENSE AGREEMENT

1. **Defined Terms.** As used in this Article and Video License Agreement, the following terms shall have the following meanings: **"Agreement"** means this Article and Video License Agreement; **"Article"** means the article specified on the last page of this Agreement, including any associated materials such as texts, figures, tables, artwork, abstracts, or summaries contained therein; **"Author"** means the author who is a signatory to this Agreement; **"Collective Work"** means a work, such as a periodical issue, anthology or encyclopedia, in which the Materials in their entirety in unmodified form, along with a number of other contributions, constituting separate and independent works in themselves, are assembled into a collective whole; **"CRC License"** means the Creative Commons Attribution-Non Commercial-No Derivs 3.0 Unported Agreement, the terms and conditions of which can be found at: <http://creativecommons.org/licenses/by-nc-nd/3.0/legalcode>; **"Derivative Work"** means a work based upon the Materials or upon the Materials and other pre-existing works, such as a translation, musical arrangement, dramatization, fictionalization, motion picture version, sound recording, art reproduction, abridgment, condensation, or any other form in which the Materials may be recast, transformed, or adapted; **"Institution"** means the institution, listed on the last page of this Agreement, by which the Author was employed at the time of the creation of the Materials; **"JOVE"** means MyJove Corporation, a Massachusetts corporation and the publisher of *The Journal of Visualized Experiments*; **"Materials"** means the Article and / or the Video; **"Parties"** means the Author and JOVE; **"Video"** means any video(s) made by the Author, alone or in conjunction with any other parties, or by JOVE or its affiliates or agents, individually or in collaboration with the Author or any other parties, incorporating all or any portion of the Article, and in which the Author may or may not appear.

2. **Background.** The Author, who is the author of the Article, in order to ensure the dissemination and protection of the Article, desires to have the JOVE publish the Article and create and transmit videos based on the Article. In furtherance of such goals, the Parties desire to memorialize in this Agreement the respective rights of each Party in and to the Article and the Video.

3. **Grant of Rights in Article.** In consideration of JOVE agreeing to publish the Article, the Author hereby grants to JOVE, subject to **Sections 4 and 7** below, the exclusive, royalty-free, perpetual (for the full term of copyright in the Article, including any extensions thereto) license (a) to publish, reproduce, distribute, display and store the Article in all forms, formats and media whether now known or hereafter developed (including without limitation in print, digital and electronic form) throughout the world, (b) to translate the Article into other languages, create adaptations, summaries or extracts of the Article or other Derivative Works (including, without limitation, the Video) or Collective Works based on all or any portion of the Article and exercise all of the rights set forth in (a) above in such translations, adaptations, summaries, extracts, Derivative Works or Collective Works and (c) to license others to do any or all of the above. The foregoing rights may be exercised in all media and formats, whether now known or hereafter devised, and include the right to make such modifications as are technically necessary to exercise the rights in other media and formats. If the "Open Access" box has been checked in **Item 1** above, JOVE and the Author hereby grant to the public all such rights in the Article as provided in, but subject to all limitations and requirements set forth in, the CRC License.

ARTICLE AND VIDEO LICENSE AGREEMENT

4. Retention of Rights in Article. Notwithstanding the exclusive license granted to JoVE in **Section 3** above, the Author shall, with respect to the Article, retain the non-exclusive right to use all or part of the Article for the non-commercial purpose of giving lectures, presentations or teaching classes, and to post a copy of the Article on the Institution's website or the Author's personal website, in each case provided that a link to the Article on the JoVE website is provided and notice of JoVE's copyright in the Article is included. All non-copyright intellectual property rights in and to the Article, such as patent rights, shall remain with the Author.

5. Grant of Rights in Video – Standard Access. This **Section 5** applies if the "Standard Access" box has been checked in **Item 1** above or if no box has been checked in **Item 1** above. In consideration of JoVE agreeing to produce, display or otherwise assist with the Video, the Author hereby acknowledges and agrees that, Subject to **Section 7** below, JoVE is and shall be the sole and exclusive owner of all rights of any nature, including, without limitation, all copyrights, in and to the Video. To the extent that, by law, the Author is deemed, now or at any time in the future, to have any rights of any nature in or to the Video, the Author hereby disclaims all such rights and transfers all such rights to JoVE.

6. Grant of Rights in Video – Open Access. This **Section 6** applies only if the "Open Access" box has been checked in **Item 1** above. In consideration of JoVE agreeing to produce, display or otherwise assist with the Video, the Author hereby grants to JoVE, subject to **Section 7** below, the exclusive, royalty-free, perpetual (for the full term of copyright in the Article, including any extensions thereto) license (a) to publish, reproduce, distribute, display and store the Video in all forms, formats and media whether now known or hereafter developed (including without limitation in print, digital and electronic form) throughout the world, (b) to translate the Video into other languages, create adaptations, summaries or extracts of the Video or other Derivative Works or Collective Works based on all or any portion of the Video and exercise all of the rights set forth in (a) above in such translations, adaptations, summaries, extracts, Derivative Works or Collective Works and (c) to license others to do any or all of the above. The foregoing rights may be exercised in all media and formats, whether now known or hereafter devised, and include the right to make such modifications as are technically necessary to exercise the rights in other media and formats. For any Video to which this Section 6 is applicable, JoVE and the Author hereby grant to the public all such rights in the Video as provided in, but subject to all limitations and requirements set forth in, the CRC License.

7. Government Employees. If the Author is a United States government employee and the Article was prepared in the course of his or her duties as a United States government employee, as indicated in **Item 2** above, and any of the licenses or grants granted by the Author hereunder exceed the scope of the 17 U.S.C. 403, then the rights granted hereunder shall be limited to the maximum rights permitted under such

statute. In such case, all provisions contained herein that are not in conflict with such statute shall remain in full force and effect, and all provisions contained herein that do so conflict shall be deemed to be amended so as to provide to JoVE the maximum rights permissible within such statute.

8. Likeness, Privacy, Personality. The Author hereby grants JoVE the right to use the Author's name, voice, likeness, picture, photograph, image, biography and performance in any way, commercial or otherwise, in connection with the Materials and the sale, promotion and distribution thereof. The Author hereby waives any and all rights he or she may have, relating to his or her appearance in the Video or otherwise relating to the Materials, under all applicable privacy, likeness, personality or similar laws.

9. Author Warranties. The Author represents and warrants that the Article is original, that it has not been published, that the copyright interest is owned by the Author (or, if more than one author is listed at the beginning of this Agreement, by such authors collectively) and has not been assigned, licensed, or otherwise transferred to any other party. The Author represents and warrants that the author(s) listed at the top of this Agreement are the only authors of the Materials. If more than one author is listed at the top of this Agreement and if any such author has not entered into a separate Article and Video License Agreement with JoVE relating to the Materials, the Author represents and warrants that the Author has been authorized by each of the other such authors to execute this Agreement on his or her behalf and to bind him or her with respect to the terms of this Agreement as if each of them had been a party hereto as an Author. The Author warrants that the use, reproduction, distribution, public or private performance or display, and/or modification of all or any portion of the Materials does not and will not violate, infringe and/or misappropriate the patent, trademark, intellectual property or other rights of any third party. The Author represents and warrants that it has and will continue to comply with all government, institutional and other regulations, including, without limitation all institutional, laboratory, hospital, ethical, human and animal treatment, privacy, and all other rules, regulations, laws, procedures or guidelines, applicable to the Materials, and that all research involving human and animal subjects has been approved by the Author's relevant institutional review board.

10. JoVE Discretion. If the Author requests the assistance of JoVE in producing the Video in the Author's facility, the Author shall ensure that the presence of JoVE employees, agents or independent contractors is in accordance with the relevant regulations of the Author's institution. If more than one author is listed at the beginning of this Agreement, JoVE may, in its sole discretion, elect not take any action with respect to the Article until such time as it has received complete, executed Article and Video License Agreements from each such author. JoVE reserves the right, in its absolute and sole discretion and without giving any reason therefore, to accept or decline any work submitted to JoVE. JoVE and its employees, agents and independent contractors shall have

ARTICLE AND VIDEO LICENSE AGREEMENT

full, unfettered access to the facilities of the Author or of the Author's institution as necessary to make the Video, whether actually published or not. JoVE has sole discretion as to the method of making and publishing the Materials, including, without limitation, to all decisions regarding editing, lighting, filming, timing of publication, if any, length, quality, content and the like.

11. **Indemnification.** The Author agrees to indemnify JoVE and/or its successors and assigns from and against any and all claims, costs, and expenses, including attorney's fees, arising out of any breach of any warranty or other representations contained herein. The Author further agrees to indemnify and hold harmless JoVE from and against any and all claims, costs, and expenses, including attorney's fees, resulting from the breach by the Author of any representation or warranty contained herein or from allegations or instances of violation of intellectual property rights, damage to the Author's or the Author's institution's facilities, fraud, libel, defamation, research, equipment, experiments, property damage, personal injury, violations of institutional, laboratory, hospital, ethical, human and animal treatment, privacy or other rules, regulations, laws, procedures or guidelines, liabilities and other losses or damages related in any way to the submission of work to JoVE, making of videos by JoVE, or publication in JoVE or elsewhere by JoVE. The Author shall be responsible for, and shall hold JoVE harmless from, damages caused by lack of sterilization, lack of cleanliness or by contamination due to the making of a video by JoVE its employees, agents or independent contractors. All sterilization, cleanliness or decontamination procedures shall be solely the responsibility of the Author and shall be undertaken at the Author's

expense. All indemnifications provided herein shall include JoVE's attorney's fees and costs related to said losses or damages. Such indemnification and holding harmless shall include such losses or damages incurred by, or in connection with, acts or omissions of JoVE, its employees, agents or independent contractors.

12. **Fees.** To cover the cost incurred for publication, JoVE must receive payment before production and publication the Materials. Payment is due in 21 days of invoice. Should the Materials not be published due to an editorial or production decision, these funds will be returned to the Author. Withdrawal by the Author of any submitted Materials after final peer review approval will result in a US\$1,200 fee to cover pre-production expenses incurred by JoVE. If payment is not received by the completion of filming, production and publication of the Materials will be suspended until payment is received.

13. **Transfer, Governing Law.** This Agreement may be assigned by JoVE and shall inure to the benefits of any of JoVE's successors and assignees. This Agreement shall be governed and construed by the internal laws of the Commonwealth of Massachusetts without giving effect to any conflict of law provision thereunder. This Agreement may be executed in counterparts, each of which shall be deemed an original, but all of which together shall be deemed to be one and the same agreement. A signed copy of this Agreement delivered by facsimile, e-mail or other means of electronic transmission shall be deemed to have the same legal effect as delivery of an original signed copy of this Agreement.

A signed copy of this document must be sent with all new submissions. Only one Agreement required per submission.

TO: JoVE editorial staff

SUBJECT: Author response to reviewer comments for JoVE manuscript 55200_R1_072716

Dear JoVE Editors,

Thank you for the reviewer comments provided for our manuscript, JoVE 55200, *Psychophysiological Assessment of the Effectiveness of Emotion Regulation Strategies in Childhood*. We believe we have addressed all of comments and have made the requested changes and edits. The editorial and reviewer comments are pasted below, with our responses to each underneath. Please let us know if further revisions are necessary. We look forward to hearing from you soon.

Best,

Liz

Editorial comments:

FORMATTING

1. Please include spaces between all steps and substeps for consistency. For instance, 9.2 and 9.2.1.

We have added spaces between all steps and substeps of the protocol as requested.

2. Lines 439 – 471 of the results section should either be reformatted so that imperative tense is not used, or moved from the results section to make a separate section of the protocol for data analysis.

We have moved this section to the end of the protocol, to a new “Data Analysis” section (p.10-11).

3. Length is currently at the maximum highlighted limit.

After making the requested changes to the manuscript, we carefully checked that our highlighted sections (~2.75 pages) did not exceed the maximum length for the filmed portion of the protocol.

GRAMMAR

4. 4.1 – Please use imperative tense or convert to a note.

We changed the language used for step 4.1 to use imperative tense.

5. In the notes, use “Instructor says” rather than “Instructor say.”

We have changed this throughout the protocol for all relevant notes.

VISUALIZATION

6. 1.1 – It is not clear how we would visualize this for filming. Please unhighlight or provide a visual representation (chart, diagram) as a supplementary file.

We un-highlighted section 1.1

7. 9.5.1, 9.6 – Spreadsheet manipulations are not suitable for filming and should not be highlighted.

We un-highlighted steps 9.5.1 and step 9.6 from the protocol on page 10, lines 419-425.

ADDITIONAL DETAIL IS REQUIRED

8. 10.1 – What are XX methods?

We have rewritten this sentence to clarify that we are referring to the methods of calculating RSA reactivity described in the subsequent steps.

9. If your figures and tables are original and not published previously, please ignore this comment. For figures and tables that have been published before, please include phrases such as “Re-print with permission from (reference#)” or “Modified from..” etc. And please send a copy of the re-print permission for JoVE’s record keeping purposes.

We do not include any previously published tables or figures in this manuscript.

10. JoVE reference format requires that the DOIs are included, when available, for all references listed in the article. This is helpful for readers to locate the included references and obtain more information. Please note that often DOIs are not listed with PubMed abstracts and as such, may not be properly included when citing directly from PubMed. In these cases, please manually include DOIs in reference information.

We checked the references to ensure DOIs were included for all references listed in the article when available.

11. IMPORTANT: Please copy-edit the entire manuscript for any grammatical errors you may find. The text should be in American-English only. This editing should be performed by a native English speaker (or professional copyediting services) and is essential for clarity of the protocol and the manuscript. Please thoroughly review the language and grammar prior to resubmission. Your JoVE editor will not copy-edit your manuscript and any errors in your submitted revision may be present in the published version.

We have carefully reviewed the manuscript for grammatical and typographical errors.

Manuscript Summary:

This is an interesting manuscript that presents novel information on measuring emotion regulation in children. It is challenging to assess emotional states in children while collecting physiologic measures. The authors present a logical protocol that is complex in nature. There are several aspects of the manuscript that need to be clarified so the reader can follow the protocol more clearly.

Major Concerns:

One over-riding concern is the use of a baseline or resting measure that is not a video yet the emotion-evoking videos are used as a comparison state. It is known that autonomic nervous system and physiologic measures differ based on the context of the condition. Attending to a video monitor will decrease heart rate and thus, increase RSA. This study limitation should be addressed in the manuscript. (for example, see Bush, N et al., Journal of Experimental Child Psychology. 110: 62-79, 2011). The lack of a video baseline will overestimate the physiologic response attributed to any emotion evoked during a video.

This is an excellent point, and highlights the imprecision in interpreting the absolute magnitude of physiological change as informative in its own right. This, however, is not the aim of the current protocol--the overestimation of physiological response is somewhat less concerning (in our opinion) when comparing magnitude of reactivity within experimental conditions to that within a control condition. Though the representative data we present in the manuscript comes from a study in which the baseline episode did not involve viewing a video clip, we have added the suggestion to use a neutral video as a baseline in our Limitations section (p.13, lines 553-555), and do not make claims about the absolute magnitude of the physiological response to the videos.

Minor Concerns:

1. P. 2 line 76 - include specific outcomes of interest with citations. What types of 'social, emotional, and cognitive outcomes'?

We added examples of social, emotional, and cognitive outcomes with citations to page 2, line 76 of the introduction.

2. P. 3 line 119; Ref #18 is not appropriate here; it is not a key RSA reference - there are better references on RSA; This article is about RSA reactivity and not a descriptive study of RSA measures. (See Berntson articles)

We substituted our original citation for two more relevant papers (p.3). We also updated the reference section to reflect this change (and other changes to the references throughout the revised manuscript).

3. P. 3 lines 128-133 should be moved up in the paragraph so you explain RSA resting before you explain RSA reactivity;

We appreciate this suggestion for revising this section of the text, because it also allowed us to address R2's minor comment #6. We moved the two sentences explaining resting RSA on page 3 to appear before the sentences on RSA reactivity.

4. P. 4 line 159 - who is in the control group? It is unclear if there is a control or baseline condition or a control group.

We clarified (page 4, lines 156-159) that step 1.1 of the protocol refers to a control condition in which no ER strategy instructions are given. We also added to the note accompanying this step of the protocol that equal numbers of children should be assigned to each condition.

5. Use the term baseline or rest but they are used interchangeably in the manuscript

We edited the manuscript so that we use the term “baseline” RSA consistently throughout.

6. P. 6 line 234 'listen to their hearts'; the Mindware acquisition software and the electrodes will monitor the child's heart rate but there is no person listening to the child's HR so it is incorrect to say 'listen'. You monitor or watch the child's HR on the computer screen.

We changed the word “listen” to “monitor” (page 6, line 238) in the text to address this.

7. P. 6 line 250 'a few moments'; be specific; it is necessary to wait 5 minutes while the electrodes adhere to the skin to provide an accurate conduction before you collect CVR data;

We edited the text to specify that researchers should give children 5 minutes to acclimate to wearing the sensors before acquiring the baseline measure (page 6, line 253).

8. P. 6 line 265-6; the electrodes includes a gel with chemicals and it is recommended that children not play with the gel and for parents or researchers to wash their hands with soap and water after touching the electrodes; thus, it is not recommended that children take off the electrodes at home without adequate supervision and handwashing;

We deleted the step describing the option to allow children to keep the electrodes to be taken home from this page.

9. P. 9 lines 379-381; RSA is not just a measure of HR, it accounts for respiration (inhalation and expiration) which changes HR;

This is an excellent point. We deleted reference to “heart rate” in our description of the software program and clarified that the software program is Mindware Heart Rate *Variability* (page 9, line 386). We also explain elsewhere (p.3, lines 118-119) that RSA is derived from the measurement of HRV within the respiratory cycle, as noted by the reviewer.

10. P. 10 lines 423-426; the calculation of reactivity is nicely stated here but the tasks involved with rest and challenge is not clear here;

We edited the text (10.1.1) to clarify the tasks involved in baseline (sitting quietly) and challenge (viewing an emotion-eliciting film) tasks for the RSA reactivity calculations.

11. Figures 2, 3 - Are there different children in each bar; include the # of children in each bar and if they are the same children with comparison conditions or comparison children;

We edited the figure labels for Figures 2 and 3 to clarify that data are presented for between-subjects experimental conditions, so bars represent different children. As noted in our response to R1's 4th minor point, we have clarified that children are equally distributed across the six different emotion and ER conditions. Because we present representative data for descriptive purposes in the figures only, we have opted not to include the exact number of children described by each bar in the graphs. However, the total sample size from which these representative data are drawn is $N = 184$, and approximately 30 children are represented by each of the 6 experimental condition bars. If advised to add this specific quantitative information to the manuscript, we will do so.

Additional Comments to Authors:

Manuscript Summary:

N/A

Major Concerns:

1) I think the introduction could do a better job of differentiating this protocol from what has been done in prior work. Specifically, the authors mention examples of how RSA reactivity on various paradigms predicts emotion regulation but not how RSA during the act of emotion regulation might track regulatory ability (which the protocol described purports to do). I think it's important to make this point clearer.

We agree that this important contribution of the protocol should be made clearer. We have revised the last paragraph of the introduction (p. 4, lines 143-146) to more explicitly highlight the novelty and innovation of the methodology we present.

2) The introduction ought to more clearly describe why sad and scary clips were used and why no neutral stimuli are used. Are the authors suggesting that experimenters could use one or the other? Are there different hypotheses regarding RSA for sad or scary emotions? And why no neutral clips? The latter of these points is particularly important because it is a marked deviation from typical reappraisal and distraction paradigms.

As described on p.2 of our introduction, sadness and fear are negative emotions that are commonly experienced by children, so understanding children's regulation of these experiences is of interest to developmentalists. We present the paradigm as using a between-subjects design, but in previous work from our group we have utilized a within-subjects design (each individual experiences each emotion, while receiving only one set of emotion regulation instructions; Davis, Quinones-Camacho, & Buss, 2015). We edited the note appearing after step 1.1 of the protocol to clearly explain that other experimental conditions and configurations can be used, depending on the research question of interest. Given the preliminary nature of this kind of work (very little is known about the physiological effects of children's active regulation of negative emotions), we do not have specific hypotheses pertaining to sadness versus fear.

We also edited the note appearing after step 7.1 of the protocol (p.8, lines 324-328) to emphasize that any emotion of interest could be examined, rather than suggesting that this approach be limited to sadness and fear.

3) Either the introduction or the protocol needs to more fully address the significance of participant age. Right now, "children" are described as a broad category in the introduction and the protocol section does not indicate what ages this procedure is suitable for, save to say that verbal assent is preferred for children under 7. Do the authors have recommendations for what the youngest ages are that a child can learn to reappraise? Are there certain pitfalls that scientists should be aware of with regards to collecting RSA in young children (e.g., greater propensity for motion-related artifacts)? What ages qualify as "younger" or "older" children in the protocol steps? These are just a few of the kinds of questions that ought to be addressed by the authors.

As developmental psychologists, we agree that these are important issues to consider when undertaking physiological assessment of children's emotion regulation. To address the

reviewer's suggestions, we have added a clarification about the age at which children are expected to be able to use distraction and reappraisal (age 5-6; p. 2, lines 86-87) to the text. We have added a statement that the use of films and a seated baseline episode in this paradigm are likely to minimize movement artifacts (p. 13, lines 579-580). We have removed reference to "younger" and "older" children in step 5.3.1 of the protocol (in which we previously advised researchers to allow older children to place the electrodes on themselves with guidance, but to consult with parents about their preference for applying electrodes to younger children). These changes have hopefully clarified the issues pertaining to child age and methodological challenges of working with children raised by the reviewer.

4) I may have missed something, but I wasn't clear on what the specific software package was that the authors used. If someone were trying to replicate these exact steps, it would be helpful to know what the authors used. I also didn't see any notes about how to insert event markers into the physio data to indicate what part of the experiment is happening at different points in time.

We added more information about the specific software package used in this protocol to the text, along with more detailed explanation of the options for incorporating event markers for specific procedural or behavioral occurrences on p.9, lines 386-388.

5) Both reappraisal and distraction are cognitively demanding tasks, at least to some extent. Might this alter RSA? If so, this ought to be mentioned in the Discussion as a caveat.

We added this point to the limitations section of the discussion (p. 12, lines 551-553).

Minor Concerns:

1) "or alleviating" in second paragraph seems redundant

We took out the redundant wording from the paragraph (page 2 line 81).

2) "how one is thinking about an emotion" is a bit clunky - maybe "how one interprets an emotion" is clearer?

We changed the wording of this sentence (page 2 line 82) as recommended by the reviewer.

3) This is strangely worded "Following recommendations to be clear about what aspect of emotion regulation is being studied"

We deleted the confusing portion of the sentence (page 3, lines 93-4).

4) I don't follow the sentence beginning with, "Similarly, ostensibly more objective" on lines 104-107

We re-worded this sentence (page 3, lines 103-106).

5) There are several places that ought to include citations. These include:

- a. Final sentence of the first paragraph**
- b. Final sentence of second paragraph**
- c. The paragraph on lines 99-113**

We added citations for the sentences in each of these places (a: p.2, line 76; b: p.2, lines 86-87; c: p.3, lines 101-102).

6) I'm unclear from the introduction about whether higher or lower RSA reactivity to tasks is thought to index better emotion regulation (this is clarified later on, but should be clearer from the start)

We have revised the section of the introduction describing RSA patterns (p.3, lines 122-130) to provide an earlier explanation of RSA reactivity.

7) This sentence is confusing: "For example, RSA suppression (decrease from resting level) is linked to experiencing fear and sadness, but augmentation (increase from resting level) when sadness and fear are evoked via film clips"

We revised this sentence to be clearer (p.3-4, lines 137-140).

8) What do the authors deem to be acceptable interrater reliability?

We added a sentence explicitly stating that we recommend reaching 85% interrater agreement to page 10, line 421.
