oral cancer, squamous cell carcinoma, surgery, resection margin, intraoperative assessment, head and neck cancer

SUMMARY:

The goal of this protocol is to provide a clear overview of specimen-driven intraoperative assessment of resection margins. It is encouraged to implement this protocol to improve patient care at other institutes.

ABSTRACT:

The goal of head and neck oncological surgery is complete tumor resection with adequate resection margins while preserving acceptable function and appearance. For oral cavity squamous cell carcinoma (OCSCC), different studies showed that only 15%–26% of all resections are adequate. A major reason for the low number of adequate resections is the lack of information during surgery; the margin status is only available after the final histopathologic assessment, days after surgery.

The surgeons and pathologists at the Erasmus MC University Medical Center in Rotterdam started the implementation of specimen-driven intraoperative assessment of resection margins (IOARM) in 2013, which became the standard of care in 2015. This method enables the surgeon to turn an inadequate resection into an adequate resection by performing an additional resection during the initial surgery. Intraoperative assessment is supported by a relocation method procedure that allows accurate identification of inadequate margins (found on the specimen) in the wound bed.

The implementation of this protocol resulted in an improvement of adequate resections from 15%–40%. However, the specimen-driven IOARM is not widely adopted because grossing fresh tissue is counter-intuitive for pathologists. The fear exists that grossing fresh tissue will deteriorate the anatomical orientation, shape, and size of the specimen and therefore will affect the final histopathologic assessment. These possible negative effects are countered by the described protocol. Here, the protocol for specimen-driven IOARM is presented in detail, as performed at the institute.

INTRODUCTION:

Every year, around 350,000 new patients are diagnosed worldwide with cancer in the oral cavity; 90% of cases are squamous cell carcinoma¹. The mortality rate is 175,000 worldwide per year and the 5-year survival is 50% to 64.8%¹⁻⁴.

The primary treatment of oral cavity squamous cell carcinoma (OCSCC) is surgery⁵. The goal of the surgery is the complete removal of the tumor with adequate margins, according to the Royal College of Pathologists⁶. Margins >5 mm (clear) are regarded as adequate, whereas margins from 0–5 mm are regarded as inadequate.

Adequate resection margins lead to higher survival and a reduction in local recurrence-rates of OCSCC⁷⁻⁹. Tumor resections with inadequate margins result in the need for adjuvant therapy (postoperative radiotherapy and/or chemotherapy). This brings an additional burden for the patient, increasing morbidity and reducing the quality of life¹⁰. The resection margin is the only oncological prognostic factor that the surgeon and pathologist can influence.

Recent reports have shown that adequate resections are only achieved in 15%–26% of cases^{7,8,11}. These poor results are caused by the complex anatomy of the oral cavity and the lack of intraoperative guidance. During surgery, the surgeon can only rely on inspection, palpation, and preoperative imaging.

The final margin status follows only several days after the operation. If an inadequate margin is encountered at the final pathologic assessment, a second operation is usually not an option, because the wound bed reconstruction has usually healed by that time. Moreover, a second operation is mostly not effective, because the relocation of the inadequate margin is even more difficult in the postoperative setting.

To overcome the lack of intra-operative information about margin status, specimen-driven intraoperative assessment of resection margins (IOARM) was implemented in 2013⁹. It became the standard of care in the institute in 2015. Described here is the IOARM method in detail to enable colleagues at other institutes to implement this protocol.

PROTOCOL:

This study was approved by the institutional Medical Ethics Committee (MEC-2015-150).

NOTE: All the patient and personnel information in the figures or examples are fictional (i.e., XXXXX and YYYYY).

1. Before surgery

1.1. Surgery department: Request for IOARM during the planning of surgery.

1.2. Pathology department: Ensure logistics/equipment (see **Table of Materials**) and the availability of personnel (pathologist/pathology resident and assistant).

2. During surgery

2.1. Operation room (OR)

2.1.1. Ensure that all involved personnel are familiar with the relocation protocol¹².

2.1.2. Follow the relocation protocol.

2.1.3. Submerge the tags in chlorhexidine for at least 30 min before the start of the surgery.

2.1.4. Place the tags paired on either side of the intended line of resection (both superficial and deep), so that one tag is on the resection specimen and the other remains at the corresponding spot in the wound bed (**Figure 1A**) as described by Van Lanschot et al.¹².

2.1.5. Cut between each pair of tags.

2.1.6. Remove the specimen with the tumor (one tag from each pair remains in the wound bed, **Figure 1B**).

2.1.7. Fill out the pathology request form with a clear indication of the anatomical location of the tags (e.g., tag 1 = anterior, tag 2 = posterior).

2.1.8. Record the procedure-related defects in the specimen and their location in relation to the tags, on the pathology request form.

NOTE: Procedure-related defects create false resection surfaces and can lead to incorrect allocation of inadequate margins during both IOARM and final pathology.

2.1.9. Bring the specimen to the pathology department.

[Place **Figure 1** here]

2.2. IOARM – Grossing room (GR), pathology department

2.2.1. Rinse the specimen with water and gently pat it dry with gauze or paper.

NOTE: Register every next step with photographs and store them in the Electronic Patient File (EPF).

2.2.2. Record the general information (date, patient id, pathology number, surgeon, pathologist, type of specimen, and tags used) on the anatomical template.

2.2.3. Indicate the locations of the tags on the anatomical template (**Figure 2**).

2.2.4. Place the specimen on the anatomical template.

[Place **Figure 2** here]

2.2.5. Ink the resection surface according to standard protocol (e.g., superior blue and inferior green).

2.2.6. Inspect the specimen visually and by palpation (pathologist and surgeon).

2.2.7. Indicate the location of any suspicious region (i.e., margin <5 mm) on the anatomical template and relate it to the numbered tags (section **Result of IOARM, Figure 2**).

2.2.8. Perform an incision perpendicular to the resection surface at the suspicious region (**Figure 3A**). Depending on the size of the specimen and/or suspicious regions, make one or more incisions with a distance of about 5 mm. In case of more than one incision, number the incisions as IOA1, IOA2, etc.

2.2.9. Measure the margins (i.e., the distance between resection surface and tumor border) on the tissue sections (**Figure 3B**) and record the exact values in mm on the anatomical template (section **Result of IOARM, Figure 3C**).

NOTE: If the tumor border is macroscopically not distinguishable (e.g., the tumor cannot be distinguished from surrounding fibrotic or salivary gland tissue), microscopic analysis by frozen section is indicated.

[Place **Figure 3** here]

2.2.10. Proceed with the completion of the operation, step 2.2.19. If an adequate margin is detected (i.e., additional resection is not needed).

2.2.11. Indicate the exact location based on the tags if an inadequate margin is detected and record it on the template. Proceed with an additional resection if surgically/technically achievable, step 2.2.13.

2.2.12. Annotate the reason on the template, if an additional resection is not achievable (section **Additional comments, Figure 2**)

2.2.13. Recommend (pathologist/surgeon) the additional resection based on the exact location and indicate the thickness needed to achieve an adequate resection (**Figure 3C**).

NOTE: If the inadequate margin concerns a positive margin, a minimal thickness of 6 mm should be recommended for the additional resection.

2.2.14. Keep (pathologist) the main resection specimen in the refrigerator until the additional resection is received.

2.2.15. Relocate (surgeon) the area of additional resection in relation to the tags, in the wound bed, based on the record of IOARM (**Figure 3C**).

2.2.16. Perform the additional resection.

2.2.17. Send the additional resection to the GR.

2.2.18. Verify (pathologist) the accuracy of the additional resection regarding its location (based on tags) and its size.

NOTE: The above steps are applicable in the case of a close margin. In the case of a positive margin, an IOARM of the additional resection is necessary (pathologist). The surgeon waits for the result of the second IOARM before completing the operation.

2.2.19. Remove the remaining tags from the wound bed and complete the operation (surgeon).

2.2.20. Copy all data from the anatomical template to the EPF (pathologist).

3. After IOARM – Grossing room (GR), pathology department

NOTE: To preserve the anatomical orientation and shape of the specimen the following steps are performed.

3.1. Reassemble the specimen by the correct orientation of all tissue sections (cross-sections and the polar ends) based on the tags and the photographs recorded during IOARM.

NOTE: Cross-sections are in the middle of the specimen and the polar ends are the outer parts of the specimen.

3.2. Cut the pieces of cork slightly larger than the tissue sections.

3.3. Place each tissue section on a piece of cork.

3.4. Draw a line on the cork around the tissue section with a permanent marker and take a photograph (**Figure 4A**).

3.5. Place another piece of cork on top of all tissue sections except the polar ends (**Figure 4B**).

3.6. Keep the upper and lower cork together, with the tissue section in between, by placing pins through both corks next to the edge of the tissue section, but not through the tissue section (Figure 4B).

[Place Figure 4 here]

3.7. Place the polar ends on a separate piece of cork (Figure 4A).

3.8. Keep the polar ends attached to the cork by obliquely placing pins over the tissue and piercing the cork just beside the edge of the tissue (Figure 4B).

CAUTION: Do not puncture the specimen with the pins.

3.9. Reassemble the whole specimen: put all the tissue sections including the polar ends together in the correct anatomical orientation.

3.10. Keep all the tissue sections together by puncturing the adjacent corks (Figure 4C).

3.11. Position the specimen with the correct orientation on the anatomical template and take a photograph.

3.12. Place the specimen in formaldehyde solution (formalin 4%).

NOTE: For proper fixation, pieces of paper can be placed on top of the specimen to keep it submerged in formalin.

3.13. Make a clear and visible warning note on the container with the specimen (e.g., caution needles/pins), to avoid accidents.

3.14. Store the container with the specimen for further processing, according to the standard pathology protocol.

4. Grossing of the fixed specimen after IOARM

NOTE: After formalin fixation, the specimen should be grossed preferably by the pathologist/resident/assistant, who performed the IOARM.

CAUTION: Be careful with the needles/pins when removing the specimen from the container.

4.1. Follow the institutional grossing protocol.

NOTE: Take additional measures to ensure the correct orientation and to facilitate the comparison of the margin status between IOARM and final pathologic assessment.

304
305 4.1.1. Consult the pictures of the IOARM.

306
307 4.1.2. Take the specimen out of the container.

308
309 4.1.3. Check whether all the tissue sections are present.

310
311 4.1.4. Position the specimen with the correct orientation on the anatomical template and take
312 a photograph (**Figure 4D**).

313
314 4.1.5. Remove the pins.

315
316 4.1.6. Separate the individual tissue sections with corresponding cork.

317
318 4.1.7. Take photographs of each tissue section with their corresponding corks, focusing on the
319 lines that were drawn around the tissue section to assess possible shrinkage of tissue after
320 fixation (**Figure 5**).

321
322 [Place **Figure 5** here]

323
324 4.1.8. Detach all tissue sections systematically from the cork (e.g., start from anterior to
325 posterior or left to right).

326
327 4.1.9. Gross the IOARM-tissue sections to the standard final tissue sections (2–3 mm thick).

328
329 4.1.10. Place all final tissue sections, in the correct anatomical orientation (e.g., from anterior to
330 posterior), on a paper on the grossing table.

331
332 4.1.11. Number all the final tissue sections consecutively with a permanent marker on the paper
333 (**Figure 6**).

334
335 4.1.12. Annotate the location of IOARM with a permanent marker (**Figure 6**).

336
337 4.1.13. Take photographs, including all final tissue sections and store them in the EPF (**Figure 6**).

338
339 4.1.14. Select the relevant final tissue sections and IOARM sections to be further processed for
340 final pathologic assessment.

341
342 [Place **Figure 6** here]

343 344 **5. The final pathologic assessment – Impact of IOARM on final margin status**

345
346 5.1. Follow the local standardized protocol. The protocol followed here is the PALGA
347 (Pathologisch-Anatomisch Landelijk Geautomatiseerd Archief, the nationwide network and

registry of histo- and cytopathology in the Netherlands) national Head-Neck protocol for the final standardized structured pathology report.

NOTE: This protocol is based on the up-to-date standards of the American Joint Committee on Cancer (AJCC), Union for International Cancer Control (UICC), and the World Health Organisation (WHO).

5.1.1. Assess all the margins in millimeters, including mucosa, submucosa, and bone.

5.1.2. If an inadequate margin is found, annotate its extent (e.g., submucosal margin anterior is 3.5 mm, extending over a trajectory of 6 mm).

5.1.3. Assess the presence of dysplasia and its grade for mucosal resection margins.

5.1.4. Indicate the final margin by adding the dimensions of the additional resection (if performed) to the margin measured on the main specimen.

5.1.5. Record the unique pathology number of the additional resection in the pathology report of the main specimen (e.g., Margins: anterior 6 mm, posterior 8 mm, superior 6 mm (including 3mm of the additional resection, H20-2021), inferior 7 mm, medial 5.3 mm).

5.1.6. Verify the margins found during IOARM.

5.1.7. Annotate the result of this verification (e.g., NB Margins found during the intraoperative assessment are in concordance with margins based on the final pathology).

NOTE: The time needed for IOARM should be limited in order to not interfere with the surgical workflow. At the institute, the IOARM takes about 10 min. The surgeon and pathologist perform the IOARM together. For the relocation method (placing the tags during surgery) an additional time of 5 min is needed. This will differ for each institute depending on the logistics.

REPRESENTATIVE RESULTS:

Example of IOARM resulting in an adequate resection

The patient presents with a cT2N0M0 SCC of the left side of the tongue with no medical history. The patient undergoes hemiglossectomy supported by IOARM. The specimen is inspected and palpated; the mucosal margins are measured as >5 mm. One area in the submucosal resection surface is suspicious for an inadequate margin, located around tag 5. The submucosal margin is 3–4 mm at tag 5. All the information is recorded on the template and copied to the EPF (**Figure 7A**)

[Place **Figure 7** here]

The surgeon returns to the OR and performs the additional resection. The pathologist verifies the

accuracy and dimensions, including the thickness of the additional resection.

The final pathology report shows the presence of moderately differentiated pT2 squamous cell carcinoma on the left side of tongue. The tumor diameter is 2.5 cm and the depth of invasion is 6.0 mm. The worst pattern of invasion (WPOI) is category 3. Perineural invasion (PNI) is not present and the lymphovascular invasion (LVI) is present. The minimal margins (mucosal and submucosal) at the inferior, superior, anterior, and posterior location are 5.8 mm (including additional resection (PA number: XXXXX) of 3 mm thickness), 6.2 mm (including additional resection (PA number: XXXXX) of 3 mm thickness), 5.2 mm, and 5.5 mm, respectively. IOARM is in concordance with final pathology.

[Place **Table 1** here]

Example of IOARM not resulting in an adequate resection

The patient presents with a cT1N0M0 SCC of the right side of the tongue with no medical history. The patient underwent a resection supported by IOARM. The surgeon takes the specimen to the pathologist at the pathology department. The mucosa is visually inspected, and the mucosal margins are measured with a transparent ruler, all mucosal margins are >5 mm. The submucosal margins are visually inspected and palpated and all margins seem >5 mm. A suspicious area is found at tag 1 (anterior resection surface) and tag 3 (posterior resection surface). A grossing knife is placed perpendicular to the resection surface from anterior to posterior (tag 1 to tag 3) and an incision is made. The pathologist measures the margin on the cross-section and the margins are >5 mm. All the information is recorded on the template and copied to the EPF (**Figure 7B**).

The final pathology report shows a well-differentiated pT1 squamous cell carcinoma on the right side of the tongue. The diameter of the tumor is 1.8 cm, and the depth of invasion is 3.8 mm. The worst pattern of invasion (WPOI) is category 2. Perineural invasion (PNI), lymphovascular invasion (LVI), and dysplasia are not present. The minimal margins (mucosal and submucosal) at the inferior, superior, anterior, and posterior locations are 4.0 mm, 6.1 mm, 6.4 mm, and 7.8 mm, respectively. IOARM is not in concordance with final pathology, margin inferior was missed.

Table 2: Example of resection margins during IOARM not resulting in an adequate resection at final pathology.

DISCUSSION:

The goal of surgical treatment of OCSCC patients is the complete removal of the tumor with adequate margins. This is too often not achieved, which inspired to design a new approach to oral cancer surgery with a focus on the resection margin status. Aside from resection margins, other adverse tumor factors such as the pattern of invasion, perineural invasion, and lymphovascular invasion also affect the local recurrence. However, of all adverse tumor factors, surgeons and pathologists can only influence the resection margins^{7,8,11}.

The specimen-driven IOARM method was implemented in 2013; this was eventually supported by the evidence that specimen-driven IOARM is superior to defect-driven IOARM^{7,13–17}. This resulted in its recommendation by AJCC in 2017¹⁸. Noteworthy, the specimen-driven IOARM method became the standard of care in the institute in 2015. From 2013 until 2020 the IOARM was performed in 304 cases with a steep increase from 2018.

It is important to realize that developing and implementing an IOARM method involves many personnel (pathologists/surgeons/assistants/trainees/researchers), in order to make it standard of care. Many professionals were involved, during many years, in the development of this protocol, which is actually the strength of the method. The development of this method started in 2013 and reached a consensus in 2015. This was achieved based on the two-weekly meetings

during which discussions regarding all the patients treated with surgery, including IOARM, took place. In this way, it was possible to timely adjust and refine the procedure. Besides, the two-weekly meetings enabled prospective data collection, which provides the basis for the performance and follow-up studies⁹. Moreover, for every case, the team ensured that the final pathology was not compromised due to IOARM. Finally, it is important to realize that this kind of assessment is a dynamic process and will always undergo changes toward improvement.

With the specimen-driven IOARM method, the margins are assessed by inspection, palpation, and perpendicular incisions (grossing). This approach provides an as accurate as possible estimation of margins in millimeters and enables feedback on whether an additional resection is needed and what the dimensions should be. Kubik et al. described several reasons (e.g., additional resection at an incorrect location, the incorrect orientation of the additional resection, incorrect dimensions of the additional resection) for additional resections to be inadequate¹⁷. The IOARM is a valuable method but only when accompanied by an as accurate as possible relocation method of inadequate margins to enable the surgeon to perform an adequate additional resection. The spatial relationship between the additional resection and the main specimen is the key factor. Therefore, a simple but elegant relocation method as shown in **Figure 1** was developed and described in detail by Van Lanschot et al.¹². This method allows the surgeon to perform an additional resection based on the relocation of the inadequate margin defined by the tags in the wound bed. For example, a margin of 2 mm is found between tags 1–2–3, the surgeon performs an additional resection around tags 1–2–3 with a thickness of 4 mm. This relocation method is shown to be effective by the results of Smits et al.⁹.

This IOARM method is supported by frozen section procedure only if the tumor cannot be distinguished macroscopically from surrounding tissue (e.g., fibrosis of tissue after radiotherapy or scar formation after previous surgery, or salivary gland tissue). Some institutes use another approach, in which frozen sections are taken from the specimen from all quadrants^{13,19}. This method enables a more standardized protocol. However, the comprehensiveness of this method might not be always efficient. Moreover, multiple frozen sections are needed which is costly, time-consuming, and not accessible for all institutes. The described method is more efficient because the region of interest is preselected (i.e., region of suspicious inadequate margin) and is therefore cheaper, faster, and available for every institute. This is in accordance with previous findings that frozen section analysis does not improve the accuracy of specimen-driven IOARM based on grossing in most cases and is not cost-effective^{20–22}.

According to the literature >93% of all inadequate margins are found at the submucosal resection margins²³. This is in line with the findings of the institute. Mucosal alterations with high-grade dysplasia/CIS are often easy to detect during IOARM, only in a few cases, a frozen section is recommended. Until now in the IOARM cohort, any mucosal positive margins regarding cancer or high-grade dysplasia/CIS have not been encountered.

Even though specimen-driven IOARM significantly improves the rate of adequate resections in OCSCC patients and consequently improves patient outcome^{7,9,22,21}, its wide implementation is lagging. The main cause of this is the fact that the grossing of fresh tissue is counter-intuitive for

524 pathologists. The pathologists are fearful that grossing fresh tissue will deteriorate the
525 anatomical orientation, shape, and size of the specimen, and therefore will affect the final
526 histopathologic assessment^{24,25}. However, the measures prescribed in the protocol prevent these
527 possible negative effects. Since the implementation of this protocol, the anatomical orientation,
528 shape, and size of the specimen have never been altered nor was the final pathologic assessment
529 ever compromised (manuscript in preparation).

530
531 Although little additional time is required to perform IOARM, it is clear that no real obstacles
532 exist to implement IOARM, but there must be a willingness to go through a learning curve,
533 regarding the grossing of fresh tissue and identifying inadequate margins. The most important
534 prerequisite is a dedicated and cooperative team of surgeons and pathologists. In this study, an
535 IOARM method for head and neck cancer surgery has been described, that can easily be
536 implemented in every institute and during any other cancer surgery. This protocol significantly
537 improves the rate of adequate resections while concomitantly reducing the need for
538 postoperative radiotherapy and improving the patient outcome. The specimen-driven IOARM
539 method will help surgeons to achieve first-time-right surgery and patients will benefit.

540 541 **ACKNOWLEDGMENTS:**

542 We thank Bas J. van Brakel and Roxanna Haak for their help in performing IOARM. Klara A.
543 Bouman-Zevenbergen, Ian Overduin, and Silvy L. Sabiran – Singoredjo for their assistance and
544 supportive role in ensuring logistics, equipment, and availability of personnel at the pathology
545 department.

Additional comments:	Additional resection not achievable reason:		

Margins (mm)			
Location	Based on IOARM	After additional resection	Based on Final pathology
Inferior	3-4	6-7	5.8
Superior	3-4	6-7	6.2
Anterior	>5		5.2
Posterior	>5		5.5

Margins (mm)			
Location	Based on IOARM	After additional resection	Based on Final pathology
Inferior	>5	Not recommended all margins > 5mm	4.0
Superior	>5		6.1
Anterior	6		6.4
Posterior	8		7.8

Name of Material/ Equipment	Company	Catalog Number	Comments/Description
Anatomical templates			https://www.palga.nl/assets/uploads/Protocollen/HoofdHalstum/
Anatomical tweezers			
Brush			to apply the inc to the tissue
Bucket for formalin fixation			Size of the container depends on the size fo the tissue
Buffered formalin 4%			
Camera			
Computer			
Cork			Thin plates of cork
Ethanol 70%			
Examination gloves			
Gauze or Paper			That wont leave particles on the specimen
Grossing knife 15cm			
Grossing knife 30cm			
Grossing tabel			
Inc for tissue			3 or more different colors
Labcoat			
Long pins/Sewing pins			
Paper			To place the tissue sections on during the grossing
Permanent markers			Different colors (black/blue/red/green)
Relocation tags	Premier Farnell Limited BV, Utre		Numbered froimn 0-9, cut to a size of 5 mm x 7 mm x 2 mm
Scalpel			
Surgical tweezers			
Sutures	Ethicon	Ethilon 3.0	To suture in the tags
Tap water			
Transparant ruler 30 cm			2 rulers needed

Dear Amit Krishnan,

Regarding our JoVE submission JoVE62446R1 Intraoperative assessment of resection margins in oral cavity cancer: this is the way.

1. The title can be made shorter into “Intraoperative assessment of resection margins in oral cavity cancer” However, we feel that “this is the way” adds urgency to fellow surgeons and pathologists to follow this protocol and make the step towards the improvement of patient care. We would prefer to keep the title as it is, if of course possible.
2. We have included the following on page 2 line 122 “This study was approved by the institutional Medical Ethics Committee (MEC-2015-150)”
3. We have removed some highlighted lines to fit the 3 pages.
4. This is not the usual format of a real pathology report, therefore we want to know if and why this adjustment of our original text is really necessary. If so then we will kindly accept it. We have made some minor corrections to the adjusted text.
5. We have made some minor corrections to the titles of both tables.

We noticed that 2.1 and 2.2 are not bold, could these 2 steps be made bold or be underlined?

Yours sincerely,

Yassine Aaboubout and Senada Koljenovic
